A team of physicists have taken a significant leap towards creating super-cold quantum states of matter, by achieving an average temperature of just two billionths of a degree above absolute zero. According to the theory of quantum mechanics, a particle's internal quantum state is an uncertainty of energy, not position, and as such, most quantum states are indistinguishable from each other. A quantum system can exist in a quantum state only if its energy is infinite, and all quantum states have an average kinetic energy. Qubits are the fundamental unit of quantum information, making them the ideal object to research and develop this technology, and quantum physicists have long tried to create single quantum systems, also known as qubits, at temperatures below absolute zero.

But their work has been hindered by the Heisenberg Uncertainty Principle, which limits the energy of an individual quantum system, and the infinite energy required to exist in a quantum state at extremely low temperatures. However, now physicists from the Delft University of Technology have overcome these issues by developing a system with a high-quality quantum behaviour, where the quantum state of the particles is controlled at the micro scale, opening the door to the development of quantum systems at ultra-low temperatures.
