
Telecharger .net Framework 3.5 (inclut .net 2.0 Et 3.0)

.net core is optimized to run in docker containers. the optimized image runs on x86 and arm. docker images are small and safe to run in production on any cloud or container platform with a small footprint. if you only run .net core applications you need a tiny image that is safe to deploy across many cloud providers. any other setup requires you to deploy many layers of dependent dependencies. the tinycore image is completely standalone and has no dependencies on other images or the host operating system. .net core is built for developers who want to build highly scalable and reliable services and applications. core was built from the ground up to focus on performance, the cloud, reliability and the developer experience. .net core provides a completely open source architecture, which means its completely platform independent. .net core is fully open source and available for free under an apache license. we work in an open, collaborative and transparent environment and are taking feedback from the community to help us continue to evolve the .net framework and core libraries. .net core is a general purpose development platform for building cloud-native and cloud-ready applications. write code once and run anywhere. .net core apps are written in the common language of .net and used the same code to run on client, server or cloud. you can use a variety of programming models, including .net core and xamarin. there is no reason for a framework api to require a debug build, the only thing that requires a debug build is a debug build of the compiler. both coreclr and corert do include a debug build of the compiler so that can be used to debug the code generated by the compiler. if debug is stripped, then the build should be the release build.

Telecharger .net Framework 3.5 (includ .net 2.0 Et 3.0)

the ui scenario was discussed previously. we are either going to have to introduce this structure where the user starts to select the stream, or the shell starts to record the stream and adds what it captures to the stream. or the content provider and media player can start the record (recording from the source) and may also have the ability to add the media to the stream. one of the core interfaces in the os project was created to help support the dynamic deployment of extensions. this is a wrapper around the xml file that is produced. the idea is to make it easier to deploy and manage extensions. there is an sdk that is part of the project that will provide tools to easily deploy the xml file. in a sense, this is a way to push the xml to the user. one of the things we did during the session is to define a basic set of user facing components that may be used to better define content. .net core was built with performance in mind from day 1, starting with feedback from users at the build conference and continuing with numerous performance tests and optimizations. one of the first changes that we made to increase performance was bringing the underlying implementation of the garbage collector from 32 bit generational to 64 bit generational, which resulted in significant improvements in applications with long-lived objects. and because .net core is open source, we could iterate on the garbage collector and develop the next generation of the microsoft garbage collector in a fresh codebase. the new microsoft gc finally ships as a standalone nuget package and is part of .net core, which makes it easier to use on more platforms. 5ec8ef588b
